

Project Design Phase

Proposed Solution

Auto Ticket Classification using Flow Designer

Date	2 oct 2026
Team ID	SWTID-2026-5846
Project Name	Auto Ticket Classification using Flow Designer
Maximum Marks	2 Marks

Proposed Solution

The proposed solution is a ServiceNow-based automated ticket classification system for a school IT helpdesk. It is designed to reduce the manual effort involved in reviewing incoming IT support requests and assigning the appropriate Category and Subcategory.

S.No.	Parameter	Project-specific Description
1	1. Problem Statement (Problem to be solved)	The school IT helpdesk receives support requests for issues such as Wi-Fi connectivity, projector failures, "password or login problems, and slow computers. The current process requires IT staff to review the ticket "description and manually determine the appropriate Category and Subcategory. This adds repetitive work and can "lead to inconsistent classification.
2	2. Idea / Solution description	The solution uses a custom Incident WorkFlow table in ServiceNow together with Flow Designer. When a new ticket "is created, the flow checks the Short Description against predefined issue keywords. It then updates the ticket "with the corresponding Category and Subcategory. The solution also uses dependent Category/Subcategory choices "and sends a confirmation email to the caller after the request is processed.
3	3. Novelty / Uniqueness	The project combines a structured ServiceNow ticket form, dependent choice configuration and a no-code Flow "Designer workflow into one simple classification process. Instead of requiring the user to decide the final "classification manually, the implemented workflow applies predefined rules consistently after ticket creation. "The approach is intentionally simple and maintainable for a school IT helpdesk environment.
4	4. Social Impact / Customer Satisfaction	The solution can reduce repetitive classification work for IT support staff

		and provide a more consistent "ticket-handling process. For students and teachers, the process requires only the relevant request information "while the classification is handled by the workflow. The automated email confirmation also gives the caller "feedback that the request has been received.
5	5. Business Model (Revenue Model)	This project is primarily an academic and service-automation solution rather than a standalone commercial "product. In a real deployment, the solution could be offered as an IT helpdesk automation service to schools or "small organizations, with revenue potentially based on implementation, configuration, customization and ongoing "support. No revenue is generated by the current academic implementation.
6	6. Scalability of the Solution	The solution can be extended by adding new Categories, Subcategories and corresponding Flow Designer rules for "additional IT issue types. The same ticket table and workflow structure can support a larger set of common helpdesk "requests. Additional features such as automated assignment, SLA handling, reporting or more advanced classification "can be considered separately as future enhancements.

Solution Flow

1. Student or teacher creates an IT support ticket.
2. Caller and Short Description information are stored in the Incident WorkFlow table.
3. The Record Created trigger starts the Flow Designer workflow.
4. The workflow checks the Short Description for predefined issue keywords.
5. Category and Subcategory are automatically assigned.
6. A confirmation email is sent to the caller.

Current Classification Coverage

Issue	Category	Subcategory
WiFi / Wi-Fi	Network	Wi-Fi
Projector	Hardware	Projector
Password / Login	Access	Forgot Password
Slow / Hanging	Performance	Slow Computer

Implementation Boundary

The current solution is a rule-based Flow Designer implementation. It does not claim machine-learning classification, external API integration, predictive analytics, or commercial revenue in the current project.

Reference

This document follows the six parameters specified in the supplied Proposed Solution Template.
