

Project Development Phase

Performance Testing Report

Auto Ticket Classification using Flow Designer

Date	3 oct 2026
Team ID	SWTID-2026-5846
Project Name	Auto Ticket Classification using Flow Designer
Maximum Marks	4 Marks

1. Purpose

This document records the performance checks relevant to the Auto Ticket Classification using Flow Designer project. The project is a configuration-based ServiceNow workflow, so the testing focuses on response behavior, workflow completion, record updates and notification processing rather than high-volume load testing.

2. Performance Test Scope

Area	What is checked	Expected Result
Ticket Creation	Time taken for the ticket form to save and create a record.	Record is created successfully without unnecessary delay.
Flow Execution	Whether the Record Created flow completes the classification steps.	Category and Subcategory are updated correctly.
Dependent Choices	Loading of valid Subcategory choices after Category selection.	Relevant choices are displayed without noticeable delay.
Email Notification	Whether the Send Email action processes after ticket creation.	Confirmation email is generated for the caller.
Multiple Test Records	Behavior when several test tickets are created during validation.	Each record is processed independently and retains its own classification.

3. Performance Test Cases

ID	Scenario	Input	Expected Result	Status	Evidence
PT-01	Create Wi-Fi ticket	WiFi not working in library	Ticket saves and Network / Wi-Fi classification is applied.	Pass	Ticket + flow result screenshot
PT-02	Create projector ticket	Projector not turning on	Ticket saves and Hardware / Projector classification is applied.	Pass	Ticket + flow result screenshot
PT-03	Create password ticket	Forgot password for portal	Ticket saves and Access / Forgot Password classification is applied.	Pass	Ticket + flow result screenshot
PT-04	Create slow-computer ticket	Computer is slow and hanging	Ticket saves and Performance / Slow Computer classification is applied.	Pass	Ticket + flow result screenshot
PT-05	Notification processing	Any valid classified ticket	Caller email action is processed after the ticket workflow.	Pass	Email record / preview screenshot

4. Performance Observation

The implemented workflow uses simple conditional checks and record updates. No separate machine-learning model, external API or heavy computation is involved. Therefore, the main performance concern for this academic implementation is successful completion of the ServiceNow transaction rather than numerical throughput benchmarking.

No artificial response-time or load-test figures are reported here because the project documentation does not contain measured benchmark data. If the team captured actual timing measurements, those values can be added as evidence.

5. Performance Testing Conclusion

The configured workflow is suitable for the intended school IT helpdesk use case under the tested project scenarios. The classification rules, dependent choices and notification action complete as part of the ServiceNow workflow. Formal stress or load testing is outside the scope of the current academic implementation.
